# Nuclear composition

*Atomic nuclei of the same element have the same numbers of protons but can have different numbers of neutrons*

**Atomic mass unit**

$$1 \text{ u} = 1.66054 \times 10^{-27} \text{ kg}$$

## Some Masses in Various Units

Particle	Mass (kg)	Mass (u)	Mass (MeV/c <sup>2</sup> )
Proton	$1.6726 \times 10^{-27}$	1.007276	938.28
Neutron	$1.6750 \times 10^{-27}$	1.008665	939.57
Electron	$9.1095 \times 10^{-31}$	$5.486 \times 10^{-4}$	0.511
${}^1_1\text{H}$ atom	$1.6736 \times 10^{-27}$	1.007825	938.79

# Nuclear radii

$$R = R_0 A^{1/3}$$

$$R_0 \approx 1.2 \times 10^{-15} \text{ m} \approx 1.2 \text{ fm}$$

Find the density of the  $^{12}_6\text{C}$  nucleus.

$$2.4 \times 10^{17} \text{ kg/m}^3$$

# Mass Defect

The mass of an atomic nucleus is less than the sum of the individual masses of the free constituent protons and neutrons (according to Einstein's equation  $E=mc^2$ ) and this 'missing mass' is known as the mass defect, and represents the energy that was released when the nucleus was formed.

# Binding energy

*The missing energy that keeps a nucleus together*

Mass of ${}^1_1\text{H}$ atom	1.007825 u
+ mass of neutron	+ 1.008665 u
<hr/>	<hr/>
Expected mass of ${}^2_1\text{H}$ atom	2.016490 u

However, the measured mass of the  ${}^2_1\text{H}$  atom is only 2.014102 u

$$\Delta E = (0.002388 \text{ u})(931.49 \text{ MeV/u}) = 2.224 \text{ MeV}$$

# Binding energy

The binding energy  $E_b$  in MeV of the nucleus  ${}^A_ZX$ , which has  $N = A - Z$  neutrons, is given by

$$E_b = [Zm({}^1_1\text{H}) + Nm(n) - m({}^A_ZX)](931.49 \text{ MeV/u})$$

## Example

The binding energy of the neon isotope  $^{20}_{10}\text{Ne}$  is 160.647 MeV. Find its atomic mass.

$$E_b = [Zm({}^1_1\text{H}) + Nm(n) - m({}^A_Z\text{X})](931.49 \text{ MeV/u})$$

Here  $Z = 10$  and  $N = 10$ .

$$m({}^A_Z\text{X}) = [Zm({}^1_1\text{H}) + Nm(n)] - \frac{E_b}{931.49 \text{ MeV/u}}$$

$$m({}^{20}_{10}\text{Ne}) = [10(1.007825 \text{ u}) + 10(1.008665)] - \frac{160.647 \text{ MeV}}{931.49 \text{ MeV/u}} = 19.992 \text{ u}$$

## Example

- (a) Find the energy needed to remove a neutron from the nucleus of the calcium isotope  $^{42}_{20}\text{Ca}$ .  
(b) Find the energy needed to remove a proton from this nucleus. (c) Why are these energies different?

## Solution

- (a) Removing a neutron from  $^{42}_{20}\text{Ca}$  leaves  $^{41}_{20}\text{Ca}$ . From the table of atomic masses in the Appendix the mass of  $^{41}_{20}\text{Ca}$  plus the mass of a free neutron is

$$40.962278 \text{ u} + 1.008665 \text{ u} = 41.970943 \text{ u}$$

The difference between this mass and the mass of  $^{42}_{20}\text{Ca}$  is 0.012321 u, so the binding energy of the missing neutron is

$$(0.012321 \text{ u})(931.49 \text{ MeV/u}) = 11.48 \text{ MeV}$$

## Example

- (a) Find the energy needed to remove a neutron from the nucleus of the calcium isotope  $^{42}_{20}\text{Ca}$ .  
(b) Find the energy needed to remove a proton from this nucleus. (c) Why are these energies different?

## Solution

- (b) Removing a proton from  $^{42}_{20}\text{Ca}$  leaves the potassium isotope  $^{41}_{19}\text{K}$ . A similar calculation gives a binding energy of 10.27 MeV for the missing proton.
- (c) The neutron was acted upon only by attractive nuclear forces whereas the proton was also acted upon by repulsive electric forces that decrease its binding energy.

# Binding energy per nucleon

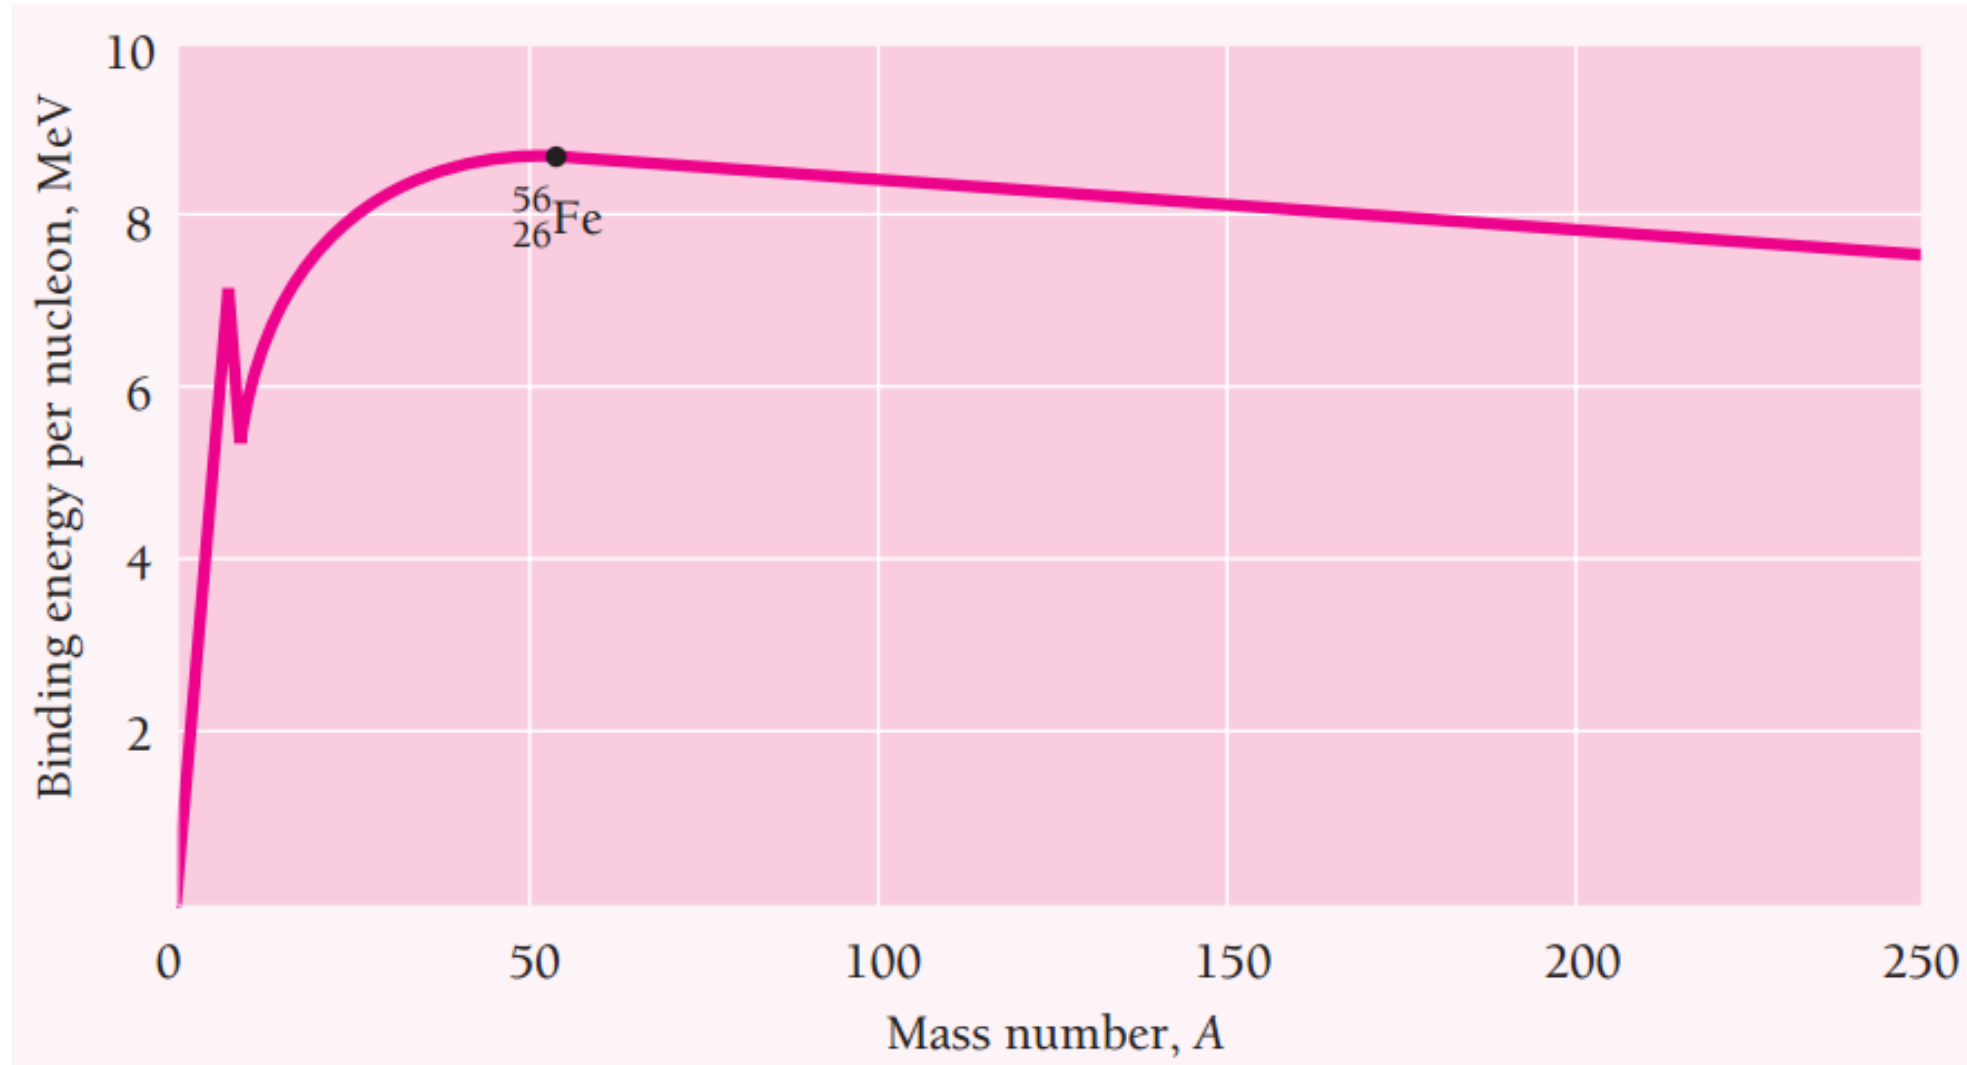

The binding energy per nucleon for a given nucleus is an average found by dividing its total binding energy by the number of nucleons it contains.

The binding energy per nucleon for  ${}^2_1\text{H}$  is  $(2.2 \text{ MeV})/2 = 1.1 \text{ MeV/nucleon}$ , and for  ${}^{209}_{83}\text{Bi}$  it is  $(1640 \text{ MeV})/209 = 7.8 \text{ MeV/nucleon}$ .

What is the binding energy per nucleon for  ${}^{235}_{92}\text{U}$ ?

The atomic mass of  ${}^{235}_{92}\text{U}$  is 234.043925 u.

# Binding energy per nucleon

# The strong interaction

The short-range attractive forces between nucleons arise from the strong interaction.

The strong interaction is what holds nucleons together to form nuclei, and it is powerful enough to overcome the electric repulsion of the positively charged protons in nuclei provided neutrons are also present to help.

Toward the end of the 19<sup>th</sup> century, minerals were found that would darken a photographic plate even in the absence of light.

This phenomenon is now called radioactivity.

Marie and Pierre Curie isolated two new elements that were highly radioactive; they are now called polonium and radium.

Henri Becquerel

Pierre Curie

Marie Curie

**The Nobel Prize in Physics 1903 for their work on radioactivity**

# Radioactivity

The emission of elementary particles by some atoms when their unstable nuclei disintegrate

## Radioactive Decay

Decay	Transformation	Example
Alpha decay	${}_Z^AX \rightarrow {}_{Z-2}^{A-4}Y + {}_2^4\text{He}$	${}_{29}^{238}\text{U} \rightarrow {}_{90}^{234}\text{Th} + {}_2^4\text{He}$
Beta decay	${}_Z^AX \rightarrow {}_{Z+1}^AY + e^-$	${}_{6}^{14}\text{C} \rightarrow {}_7^{14}\text{N} + e^-$
Positron emission	${}_Z^AX \rightarrow {}_{Z-1}^AY + e^+$	${}_{29}^{64}\text{Cu} \rightarrow {}_{28}^{64}\text{Ni} + e^+$
Electron capture	${}_Z^AX + e^- \rightarrow {}_{Z-1}^AY$	${}_{29}^{64}\text{Cu} + e^- \rightarrow {}_{28}^{64}\text{Ni}$
Gamma decay	${}_Z^AX^* \rightarrow {}_Z^AX + \gamma$	${}_{38}^{87}\text{Sr}^* \rightarrow {}_{38}^{87}\text{Sr} + \gamma$

# Radioactivity

1. Why do some nuclei decay ?
2. Why emit  $\alpha$ 's, and not protons, or neutrons ?

# Radioactivity

Activity law  $R = R_0 e^{-\lambda t}$

Radioactive decay  $N = N_0 e^{-\lambda t}$

Half-life  $T_{1/2} = \frac{\ln 2}{\lambda} = \frac{0.693}{\lambda}$

# Nuclear Reaction

# Q-value – Energetics of Nuclear Reactions

$$Q = 0.0188 \text{ amu} \times 931.481 \text{ MeV/amu} = 17.5 \text{ MeV}$$

# Q-value – Energetics of Nuclear Reactions

The **Q value** of the nuclear reaction

is defined as the difference between the rest energies of  $A$  and  $B$  and the rest energies of  $C$  and  $D$ :

$$Q = (m_A + m_B - m_C - m_D)c^2$$

If  $Q$  is a positive quantity, energy is given off by the reaction.

# Q-value – Energetics of Nuclear Reactions

The **Q-value** of this reaction is the same as the **excess kinetic energy** of the final products:

$$\begin{aligned} Q &= T_{\text{final}} - T_{\text{initial}} \\ &= (T_C + T_D) - (T_A + T_B) \end{aligned}$$

# Q-value – Energetics of Nuclear Reactions

Write down the reaction  $^{14}\text{N}(\alpha, p)^{17}\text{O}$ .

The masses of  $^{14}\text{N}$ ,  $^4\text{He}$ ,  $^1\text{H}$ , and  $^{17}\text{O}$  are respectively 14.00307 u, 4.00260 u, 1.00783 u, and 16.99913 u.

$$\begin{aligned} Q &= (14.00307 \text{ u} + 4.00260 \text{ u} - 1.00783 \text{ u} - 16.99913 \text{ u}) (931.5 \text{ MeV/u}) \\ &= -1.20 \text{ MeV} \end{aligned}$$

# Nuclear Reactions

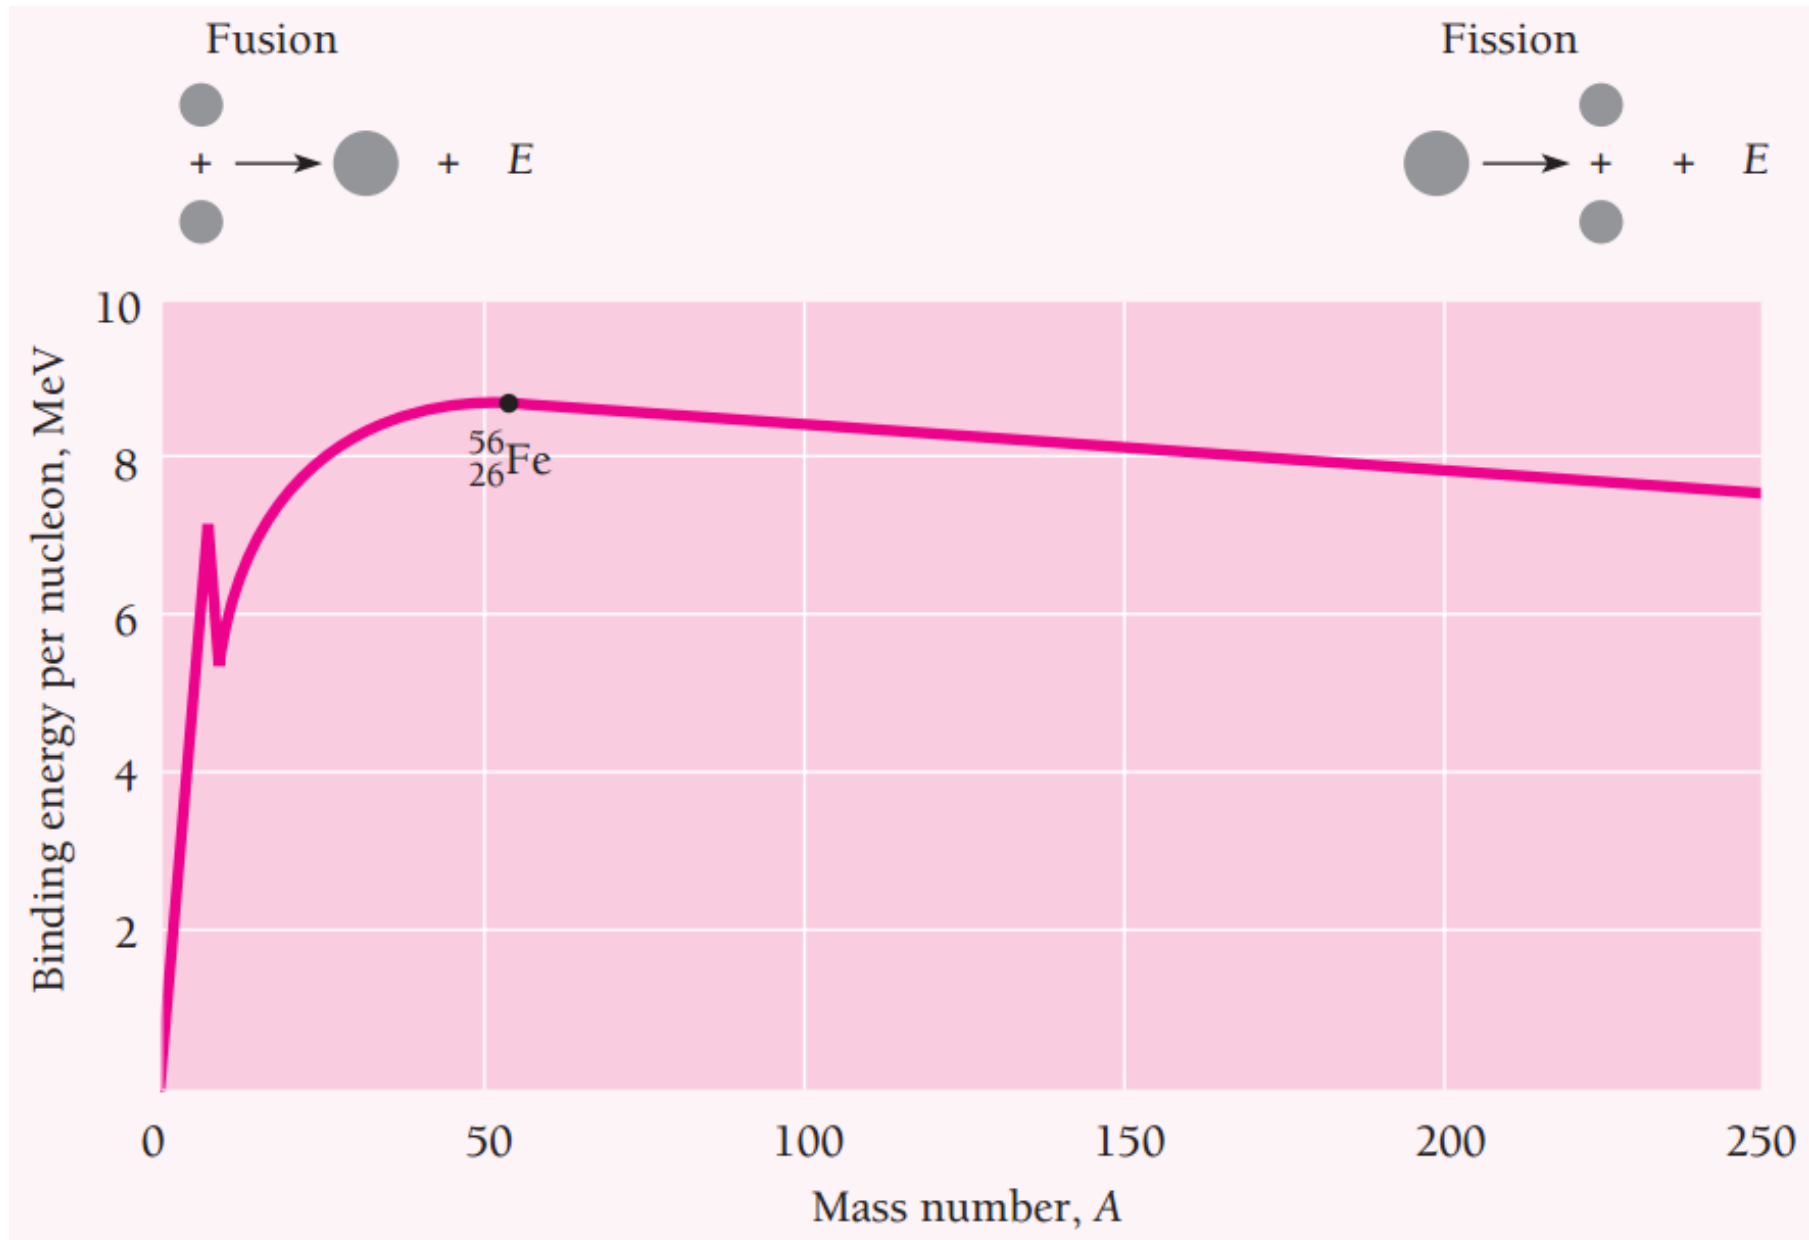

# Nuclear Reactions

# Nuclear Reactions

There are two main types of nuclear reactions: fusion and fission

In **fusion** reactions, two light nuclei are combined to form a heavier, more stable nucleus. In **fission** reactions, a heavy nucleus is split into two nuclei with smaller mass numbers. Both processes involve the exchange of huge amounts of energy: about a million times more energy than that associated with ordinary chemical reactions.

# Nuclear Fission

A nuclear reaction in which a heavy nucleus splits spontaneously or on impact with another particle, with the release of energy.

# Nuclear Fusion

Nuclear fusion is an atomic reaction in which multiple atoms combine to create a single, more massive atom. The resulting atom has a slightly smaller mass than the sum of the masses of the original atoms. The difference in mass is released in the form of energy during the reaction

The proton-proton chain reaction dominates in stars the size of the Sun or smaller.

Hydrogen bomb:  
man-made fusion device

# Nuclear Reactor

# Nuclear Reactor

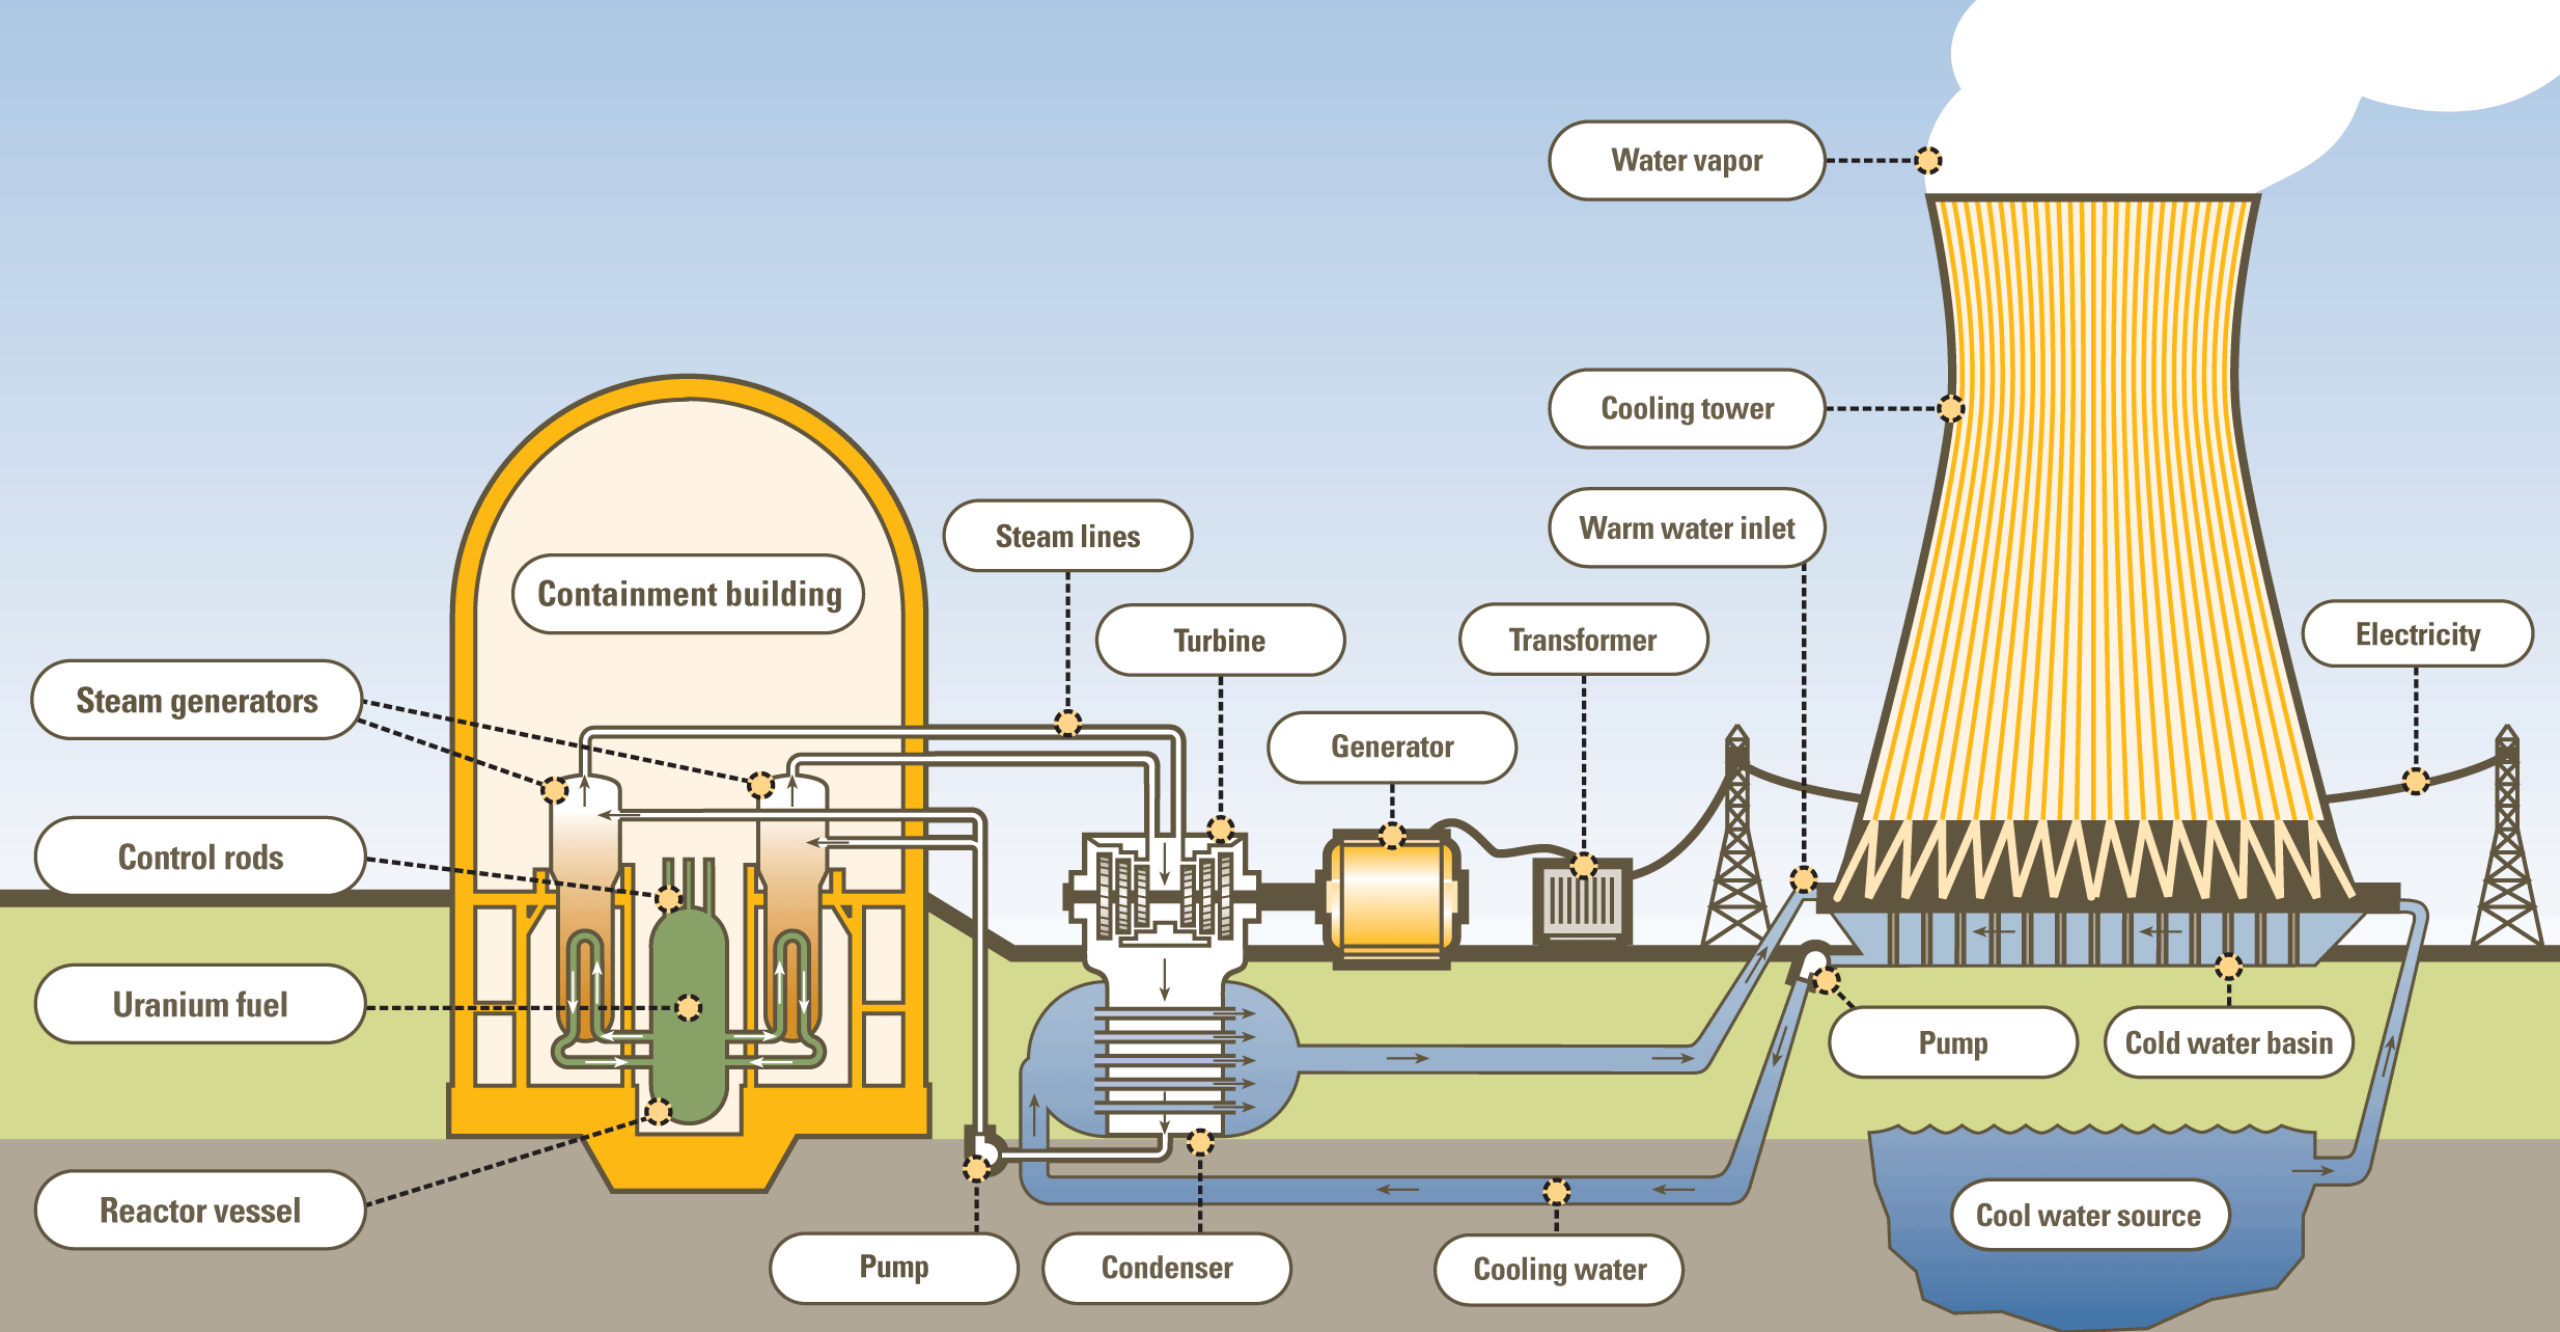

# Nuclear Reactor

A nuclear reactor is a system that contains and controls sustained nuclear chain reactions. Reactors are used for generating electricity, moving submarines, producing medical isotopes for imaging and cancer treatment, and for conducting research.

Fuel, made up of heavy atoms that split when they absorb neutrons, is placed into the reactor vessel (basically a large tank) along with a small neutron source. The neutrons start a chain reaction where each atom that splits releases more neutrons that cause other atoms to split. Each time an atom splits, it releases large amounts of energy in the form of heat. The heat is carried out of the reactor by coolant, which is most commonly just plain water. The coolant heats up and goes off to a turbine to spin a generator.

# Main components of a Nuclear Reactor

The core

The coolant

The turbine

The containment

Cooling towers

# Main components of a Nuclear Reactor

**The core** of the reactor contains all of the nuclear fuel and generates all of the heat. It contains low-enriched uranium (<5% U-235), control systems, and structural materials. The core can contain hundreds of thousands of individual fuel pins.

**The coolant** is the material that passes through the core, transferring the heat from the fuel to a turbine. It could be water, heavy-water, liquid sodium, helium, or something else. In the US fleet of power reactors, water is the standard.

**The turbine** transfers the heat from the coolant to electricity, just like in a fossil-fuel plant.

# Main components of a Nuclear Reactor

**The containment** is the structure that separates the reactor from the environment. These are usually dome-shaped, made of high-density, steel-reinforced concrete. Chernobyl did not have a containment to speak of.

**Cooling towers** are needed by some plants to dump the excess heat that cannot be converted to energy due to the laws of thermodynamics. These are the hyperbolic icons of nuclear energy. They emit only clean water vapor.

# Fusion reaction

## *The energy source of the future?*

Enormous as the energy produced by fission is, the fusion of light nuclei to form heavier ones can give out even more per kilogram of starting materials. It seems possible that nuclear fusion could become the ultimate source of energy on the earth: safe, relatively non-polluting, and with the oceans themselves supplying limitless fuel.

# Fusion reaction

## *The energy source of the future?*

Enormous as the energy produced by fission is, the fusion of light nuclei to form heavier ones can give out even more per kilogram of starting materials. It seems possible that nuclear fusion could become the ultimate source of energy on the earth: safe, relatively non-polluting, and with the oceans themselves supplying limitless fuel.

# Fusion reaction

A successful fusion reactor has three basic conditions to meet:

1. The plasma temperature must be high so that an adequate number of the ions have the speeds needed to come close enough together to react despite their mutual repulsion.
2. The plasma density must be high to ensure that collisions between nuclei are frequent.
3. The plasma of reacting nuclei must remain together for a sufficiently long time.
